

Marine Birds – Common Merganser

description

This atlas page illustrates the best available data that identifies Common Merganser habitat, derived from surveys conducted year-round. The Common Merganser (*Mergus merganser*) is a large, fish-eating diving duck with a long thin bill with serrated edges, which is used for grasping prey. The Common Merganser nests in tree cavities, and breeds along lakes or rivers bordered by forests. During winter months, this species can be found in lakes and coastal estuaries and bays.

Source data used to develop this map consisted of a range of shoreline-based, ground, boat and aerial surveys, which were focused on identifying, counting and recording marine birds. The majority of the surveys were collected at sites with defined boundaries and areas. Surveys collected along transects from each dataset were buffered depending upon observation width described within the source survey methodology in order to generate a survey area.

Observations of the listed species were totalled for each survey location and divided by the area surveyed to generate a density value for each survey location. The densities of all of the survey locations within a single planning unit were averaged and adjusted for survey effort to calculate the illustrated metric, average density of Common Merganser observations by planning unit. The values were then classified and symbolized using 5 quantiles, meaning that each class consisted of 20% of the non-zero planning units. (A quantile is established by dividing the frequency distribution of a variable into equal groups: that is, each quantile contains the same fraction of the total number of values being measured.)

All of the planning units that were surveyed, regardless of whether Common Merganser was sighted, were displayed underneath the density layer to illustrate the extent of the planning units that were surveyed.

- Representatives from Environment Canada, Canadian Wildlife Service

reviewer comments

- Common Mergansers generally breed in freshwater wetlands, and during the non-breeding season (September-March) are found more frequently in freshwater than saline habitats.

caveats of use

- Survey effort is not consistent across all planning units, across all areas of the coast or across all seasons. Areas with no data may not have been surveyed and these data gaps are not necessarily indicative of an absence of Common Merganser.
- The density values in an area can change over time in response to natural population fluctuations and changes in habitat conditions (natural or anthropogenic).
- The precision of the average density values displayed in the legend is not indicative of the original precision of the survey counts.
- This feature is a compilation of data collected by many people, for different purposes, using different survey techniques with different methodologies within each technique and, therefore, considerable care must be taken when using the data.
- Surveys performed in different seasons will produce different results.
- It is important to note that *in some cases* Coastal Waterbird Inventory surveys recorded only a subset of species present, but BCMCA did not use this information due to sheer volume and complexity of data. As a result, some areas depicted as zero density on this map may actually be 'no data' areas rather than true 'absence' data.
- Recommended date of expiry for use of these data in a marine planning context: None provided.
