

Marine Mammals – Pacific White-sided Dolphin Distribution

description

Pacific white-sided dolphins (*Lagenorhynchus obliquidens*) are known for their gregarious behaviour including aerial acrobatics and bow riding, and they are easily identified by the light patch along the front portion of their body. Dolphin teeth found in middens on Haida Gwaii indicate that Pacific white-sided dolphins have been present on the coast of British Columbia for over 2000 years. They feed on herring, salmon, other schooling fish, shrimp and squid.

Data illustrated are modelled values representing the distribution of Pacific white-sided dolphins in terms of relative densities. These density estimates are based upon dolphin observations recorded during systematic surveys in the summers of 2004, 2005 and 2006, and environmental parameters including latitude, longitude, and depth. Survey results and modelling work has been peer reviewed (Williams and O'Hara, 2010; Williams and Thomas, 2007). Distribution illustrated here is restricted to the extents surveyed (Figure 1).

Data were received in 2010 as points with values and coordinates. The points were plotted and converted to a comprehensive 2 nautical mile by 2 nautical mile grid. Density values were classified for illustration into 8 classes based on Jenks natural breaks classification. The Jenks' natural breaks classification scheme (automated in ESRI ArcGIS software) (Jenks, 1977 and Fisher, 1958) determines the best arrangement of values into classes by iteratively comparing sums of the squared difference between observed values within each class and class means. The "best" classification identifies breaks in the ordered distribution of values that minimizes within-class sum of squared differences, and thus identifies classes that are most homogenous within.

Estimated density values range from zero to five dolphins per square kilometre and the vast majority of density values are at the low end of the range.

data sources

• Rob Williams, UBC Marine Mammal Research Unit

data resolution

• Estimates were generated for midpoints of grid cells measuring 2 nautical miles by 2 nautical miles. The data are illustrated in this grid cell format.

date of analysis

• Peer-reviewed publications describing data collection and estimation of distribution and abundance were published in 2007 and 2010.

date collected

• Systematic sighting surveys were undertaken in the summers of 2004, 2005 and 2006.

reviewers

• Rob Williams, UBC Marine Mammal Research Unit

reviewer comments

• None provided.

caveats of use

- Modelled distribution is for the area covered by systematic surveys, and during the temporal extent of the surveys (Figure 1). While data are lacking for areas and seasons beyond the illustrated data, this does not imply these areas are of no importance to marine mammals.
- Opportunistic sightings data are available through the British Columbia Cetacean Sightings Network (BCCSN), through the Vancouver Aquarium. See: www.vanaqua.org/conservationinaction/killerwhales/network.htm
- Survey data for two additional years may be available from Raincoast Conservation. Recommend compiling all years of data. See: www.raincoast.org/files/WAS_report/whats_at_stake_ver1.pdf
- Recommended date of expiry for use of these data in a marine planning context: None provided.
